.com/whatsnew.html"] } Growth Performance of *Fusarium* spp. in Kiwi Fruit: Assessment by Molecular Analyses. To determine the identity and pathogenicity of *Fusarium* spp. causing rot and decay on kiwi fruit, tomato fruit, and cantaloupe fruits in the Central Valley of California during 2000-2014. Fungal isolates from decaying fruit were identified by morphological characteristics and phylogenetic analysis of partial small and large subunit (SSU and LSU) rDNA. Pathogenicity was confirmed in California kiwi fruit, tomato fruit, and cantaloupe fruit by inoculation of greenhouse-grown fruit with representative isolates of *Fusarium* spp. Fungi isolated from kiwi fruit included four morphologically similar *Fusarium* spp. and

the closely related species *F. oxysporum* (Fos), *F. acuminatum* (Fac), *F. constrictum* (Fcon), *F. venenatum* (Fven), and *F. solani* (Fsol). On kiwi fruit, *F. oxysporum* was the most prevalent species, followed by *F. constrictum*, *F. solani*, and *F. venenatum*.

Fusarium acuminatum was the second most prevalent species, followed by *F. oxysporum*, *F. constrictum*, *F. solani*, and *F. venenatum*. On tomato fruit, *F. oxysporum* was the most prevalent species, followed by *F. constrictum* and *F. solani*. *F. constrictum* and *F. solani* were closely related to isolates from kiwi fruit. On cantaloupe fruit, *F. solani* was the most prevalent species, followed by *F. oxysporum*, *F. constrictum*, and *F. venenatum*. *Fusarium solani* s.s. and *F. constrictum* were closely related to isolates from kiwi fruit, tomato fruit, and cantaloupe fruit. *Fusarium* spp. isolated from kiwi fruit exhibited low pathogenicity and the mean latent period on kiwi fruit was 98 days, and there were no significant differences in mean latent periods among the *Fusarium* spp. In greenhouse experiments, average decay incidence, average percent decay, and average percentage of decay increased with inoculum concentration. However, there were no
